Overview

Objectives: Perform extensive tests for avionics operating system – fulfil requirements of RTCA DO-178B for level A applications

- ▶ Tests in simulation environment versus on-target testing
- ▶ Generic test configuration for operating systems
- ▶ RT-Tester test automation system
- ▶ Example: ARINC 653 operating system test in Linux simulation environment with RT-Tester

Tests in simulation environment versus on-target testing

- ▶ On-target tests are required for
 - ▶ Proving functional correctness of HW/SW integration (c. f. **IMA Bare Module Tests**)
 - ▶ Achieving structural coverage on target HW (certification requirement)
- ▶ On-target tests for embedded systems usually complicate white-box testing
- ▶ On-target tests require separation of (parts of) test equipment and SUT

Tests in simulation environment versus on-target testing

Simulation environments (PC, work station)

- ▶ facilitate white-box testing
- ▶ may not be used for certification credit if simulation architecture differs “too much” from target architecture
- ▶ require special care for operating system tests:
 - ▶ For functional integration testing, conflicts between tested OS **System Under Test OS(SUT-OS)** and simulation platform OS have to be avoided – for example: Scheduler, virtual memory management and partitioning, interrupt relaying
 - ▶ Access of SUT-OS to target HW has to be stubbed – in some cases by access functions to simulation platform HW

Generic test configuration for operating systems

For functional testing:

- ▶ The non-existing application layer is replaced by **test agents** (= test applications) that exercise the **application layer interface (API)** (= APEX) of the SUT-OS
- ▶ Test agents
 - ▶ are re-usable
 - ▶ can be **remotely controlled** by testing environment
 - ▶ can exercise the most general behaviour at the SUT-OS API which is possible for “real” applications
 - ▶ may possess pre-programmed **scenarios** for robustness testing and time-critical API call sequences

Generic test configuration for operating systems

- ▶ Testing environment exercises calls to SUT-OS via **remote method invocation** to test agents
- ▶ SUT-OS is extended by **internal test functions** for
 - ▶ Checking internal data structures
 - ▶ Tracing internal behaviour of SUT-OS kernel functions
 - ▶ Tracing and storing code coverage information
- ▶ Internal test functions can be triggered by test agents via auxiliary API calls that also recover test results

Generic test configuration for operating systems

Framework for embedding SUT-OS into simulation platform: This has been performed by University of Bremen for ARINC 653 operating system implementation on Linux

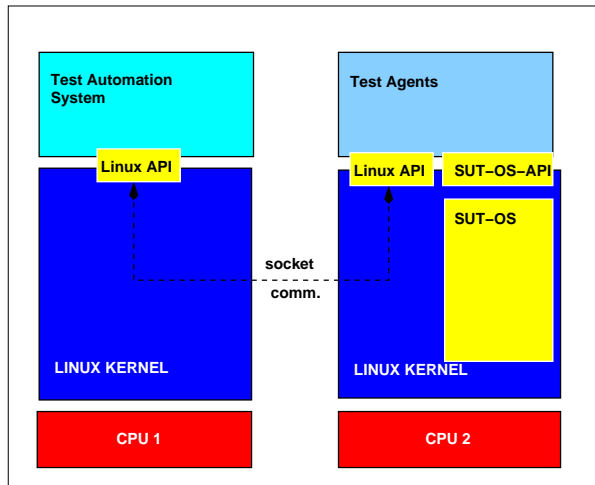

- ▶ On simulation system boot, memory is exclusively reserved for SUT-OS:
 - ▶ pages locked in memory
 - ▶ separate memory map managed by SUT-OS kernel
- ▶ Simulation platform clock interrupt triggers Linux scheduler and SUT-OS scheduler in alternation
- ▶ Configured SUT-OS processes (=partitions on ARINC 653 OS) are initialised by SUT-OS init process

Generic test configuration for operating systems

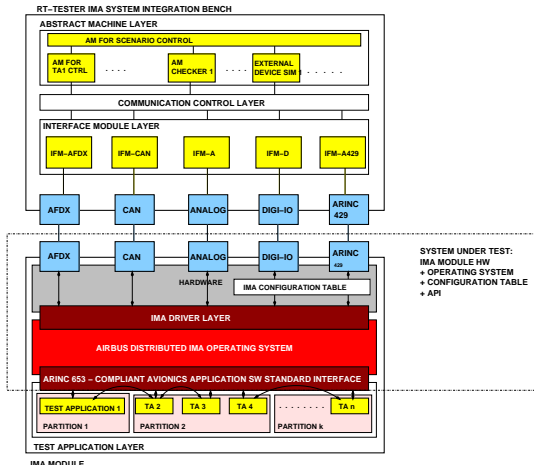

- ▶ On ARINC 653 OS, every partition runs one or more test agents (= threads of the partition)
- ▶ SUT-OS API triggers different trap (software interrupt) which leads to SUT-OS kernel instead of Linux kernel
- ▶ Test agents may combine Linux and SUT-OS API calls since these are distinguished by different traps
- ▶ Communication with testing environment is performed via TCP/IP socket communication (Linux API)

Generic test configuration for operating systems

SIMULATION ENVIRONMENT – EXAMPLE: 2-CPU PC WITH LINUX HOST OS

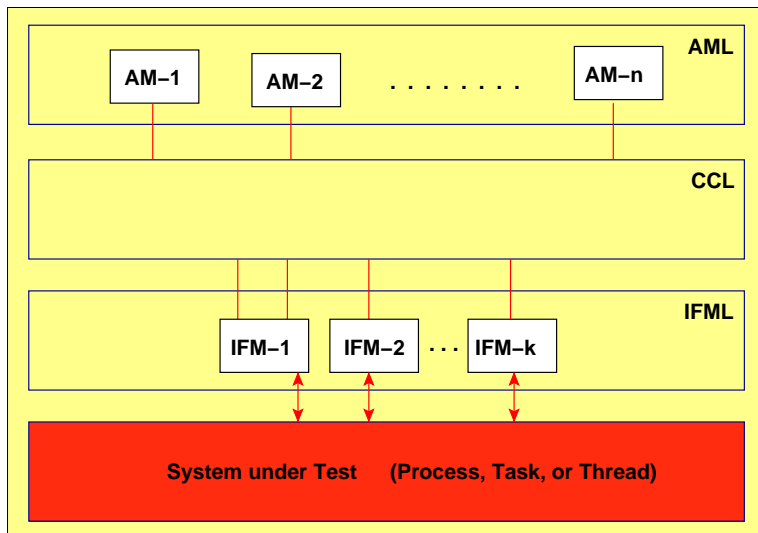

Example for On-target testing: Bare Module Tests / Configured Module Tests of IMA ARINC 653 operating system

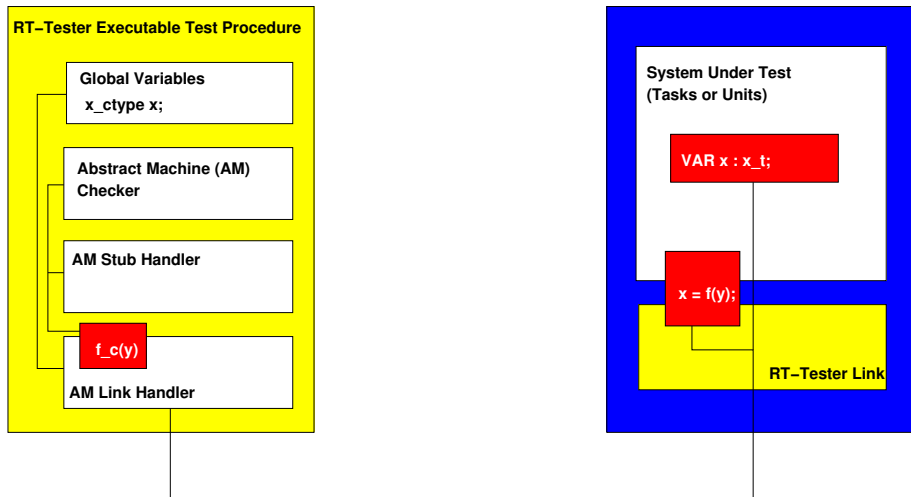

RT-Tester test automation system

- ▶ **Distributed** simulation and test system
- ▶ **Abstract machines/Interface modules** run in parallel to perform
 - ▶ Simulations
 - ▶ Automated on-the-fly checking
 - ▶ Stimulation of SUT
- ▶ Interface abstraction by means of **channels** and **vectors**
- ▶ **Hard real-time** capabilities
- ▶ Single-CPU, Multi-CPU and cluster hardware configurations available
- ▶ **Supports all testing phases** – from unit tests to system integration tests
- ▶ Provides powerful **test automation mechanisms**

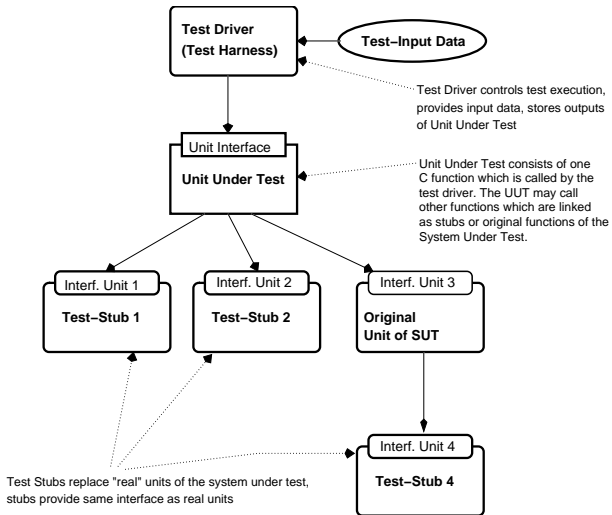

Software Integration Test with RT-Tester

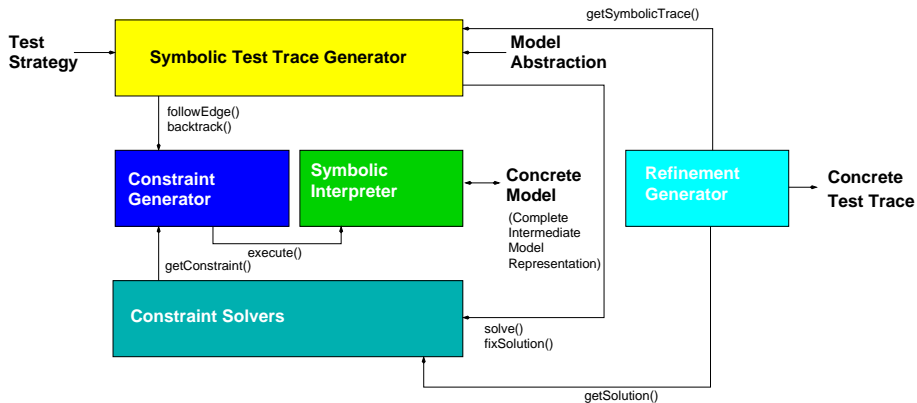

Remote Method Invocation For Test Control

Module Test Configuration

Test Cases, Test Data Generation Framework

SUT: Time-Discrete Input-Output Hybrid Systems

Initial conditions

$Init(l_1) = \text{true},$

$\forall l \in Loc - \{l_1\} : Init(l) = \text{false}$

Transition labels a, \dots, k :

$a = (l_1, \text{true},$
 $((x_1, x_2), (in_1, in_2)), l_2)$

...

$d = (l_3, x_1 < \exp(x_1 \cdot x_2),$
 $((x_1, x_2), (x_1^2 \cdot \sin(x_2), x_2)), l_4)$

...

Symbolic Test Case Tree STCT

Reachability Trees for MCDC Coverage

Example: ARINC 653 operating system test in Linux simulation environment with RT-Tester

Test examples for

- ▶ ARINC 653 semaphore mechanism
- ▶ ARINC 653 memory management
- ▶ Code coverage analysis
- ▶ Test case coverage
